

## High Input Voltage 6A PWM Converter With Low Iq

### Features

- **Adjustable Output Voltage from +0.8V to +12V**
  - 0.8V Reference Voltage
  - $\pm 1\%$  Accuracy over Temperature
- **Operates from An Input Battery Voltage Range of +2.7V to +28V**
- **Power-On-Reset Monitoring on VCC pin**
- **Excellent line and load transient responses**
- **PFM mode for increased light load efficiency**
- **Programmable PWM Frequency from 100kHz to 1000kHz**
- **Integrated 30mW at VCC=5V N-Channel MOSFET For High Side**
- **Integrated 12mW at VCC=5V N-Channel MOSFET For Low Side**
- **Integrated Bootstrap Forward P-CH MOSFET**
- **External Adjustable Soft-Start and Soft-Stop**
- **Selectable Forced PWM or automatic PFM/PWM mode**
- **Power Good Monitoring**
- **70% Under-Voltage Protection**
- **125% Over-Voltage Protection**
- **Current-Limit Protection**
  - Using Sense Low-Side MOSFET's RDS(ON)
- **Over-Temperature Protection**
- **TQFN-22 4mmx4mm package**
- **Lead Free and Green Device Available (RoHS Compliant)**

### General Description

The APW8714E is a 6A, synchronous, step-down converter with integrated 30m $\Omega$  N-channel High-Side MOSFET and 12m $\Omega$  Low-Side MOSFET. The APW8714E steps down high voltage to generate low-voltage chipset or RAM supplies in notebook computers.

The APW8714E provides excellent transient response and accurate DC voltage output in either PFM or PWM Mode. In Pulse Frequency Mode (PFM), the APW8714E provides very high efficiency over light to heavy loads with loading-modulated switching frequencies. In PWM Mode, the converter works nearly at constant frequency for low-noise requirements.

The APW8714E is equipped with accurate current-limit, output under-voltage, and output over-voltage protections, perfect for various applications. A Power-On-Reset function monitors the voltage on VCC to prevent wrong operation during power-on. The APW8714E has external adjustable soft-start and built-in an integrated output discharge method for soft stop. A soft-start ramps up the output voltage with programmable timing to reduce the start-up current. A soft-stop function actively discharges the output capacitors.

The APW8714E is available in TQFN4x4-22 (Power PAK).

### Applications

- **Notebook**
- **Mother Board**
- **Table PC**
- **Hand-Held Portable**
- **AIO PC**
- **Set-top boxes**
- **LCD TV**

## Pin Description

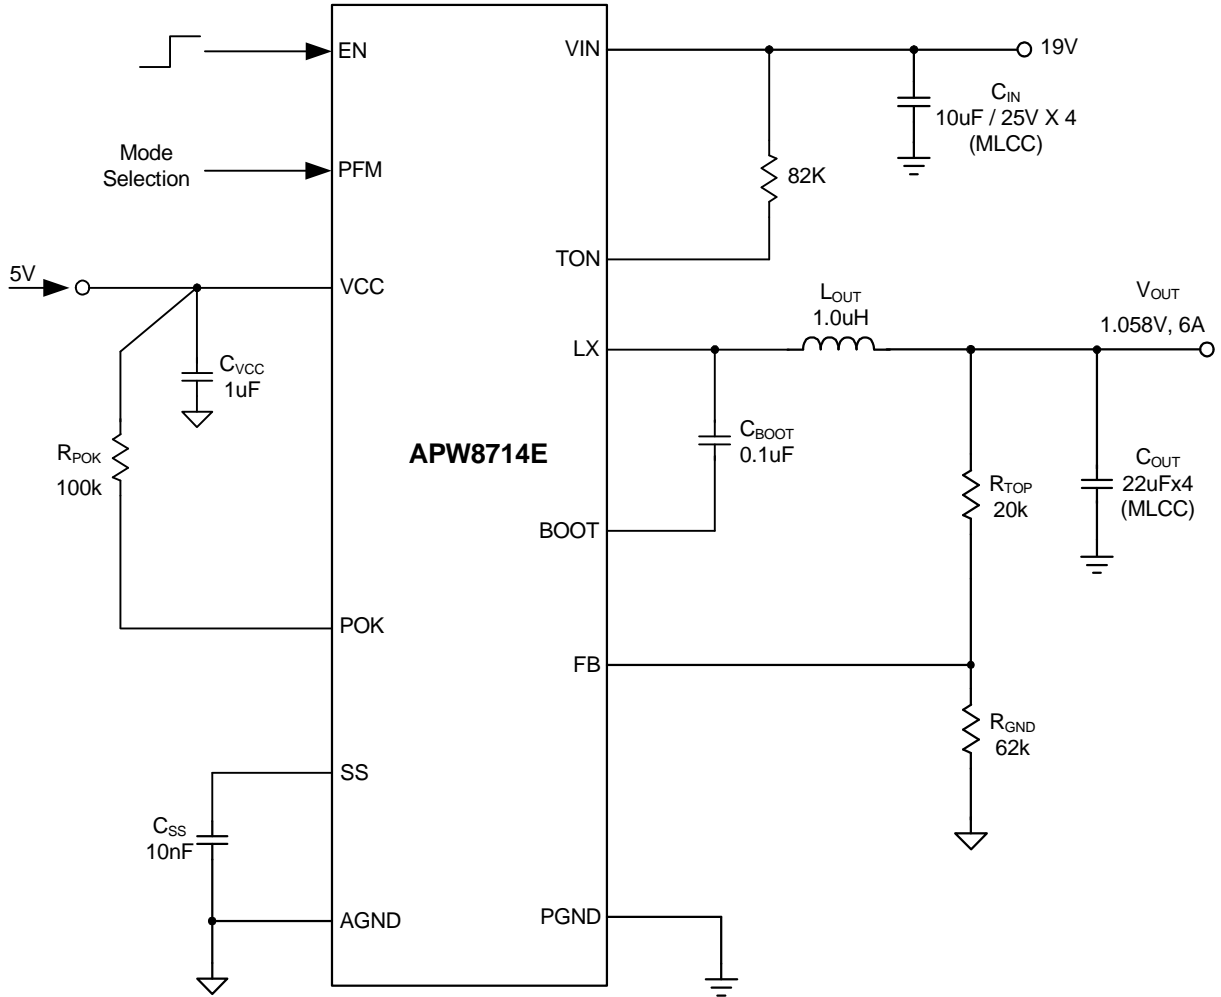

PIN		FUNCTION
NO.	NAME	
1	POK	Power-Good Output Pin of PWM. POK is an open-drain output used to indicate the status of the PWM output voltage. Connect the POK in to +5V through a pull-high resistor.
2	EN	PWM Enable. PWM is enabled when EN=1. When EN=0, PWM is in shutdown.
3	PFM	PFM Selection Input. When the PFM is above high logic level, the Device is in force PWM mode. When the PFM is below low logic level, the device is in automatic PFM/PWM Mode.
4	AGND	Signal Ground for The IC.
5	FB	Output Voltage Feedback Pin. This pin is connected to the resistive divider that set the desired output voltage. The POK, UVP, and OVP circuits detect this signal to report output voltage status.
6	TON	This Pin is Allowed to Adjust The Switching Frequency. Connect a resistor $R_{TON}$ from TON pin to VIN pin.
7, 8, 9	VIN	Battery Voltage Input Pin. VIN powers linear regulators and is also used for the constant on-time PWM on-time one-shot circuits.
10, 11, 16~18	LX	Junction Point of The High-Side MOSFET Source, Output Filter Inductor and The Low-Side MOSFET Drain for PWM. Connect this pin to the Source of the high-side MOSFET. LX serves as the lower supply rail for the UGATE high-side gate driver. LX is the current-sense input for the PWM.
12~15, 19	PGND	Power Ground of The LGATE Low-Side MOSFET Drivers.
20	BOOT	Supply Input for The UGATE Gate Driver and an internal level-shift circuit. Connect to an external capacitor to create a boosted voltage suitable to drive a logic-level N-channel MOSFET.
21	VCC	Supply Voltage Input Pin for Control Circuitry, Connect +5V from the VCC pin to the GND pin. Decoupling at least 1 $\mu$ F of a MLCC capacitor from the VCC pin to the AGND pin.
22	SS	Soft Start Output. Connect a capacitor to GND to set the soft start interval.

## Function Description

### Constant-On-Time PWM Controller with Input Feed-Forward

The constant on-time control architecture is a pseudo-fixed frequency with input voltage feed-forward. This architecture relies on the output filter capacitor's effective series resistance (ESR) to act as a current-sense resistor, so the output ripple voltage provides the PWM ramp signal. In PFM operation, the high-side switch on-time controlled by the on-time generator is determined solely by a one-shot whose pulse width is inversely proportional to input voltage and directly proportional to output voltage. In PWM operation, the high-side switch on-time is determined by a switching frequency control circuit in the on-time generator block.

The switching frequency control circuit senses the switching frequency of the high-side switch and keeps regulating it at a constant frequency in PWM mode. The design improves the frequency variation and is more outstanding than a conventional constant on-time controller, which has large switching frequency variation over input voltage, output current and temperature. Both in PFM and PWM, the on-time generator, which senses input voltage on VIN pin, provides very fast on-time response to input line transients.

Another one-shot sets a minimum off-time (typical: 250ns). The on-time one-shot is triggered if the error comparator is high, the low-side switch current is below the current-limit threshold, and the minimum off-time one-shot has timed out.

### Pulse-Frequency Modulation (PFM) Mode

In PFM mode, an automatic switchover to pulse-frequency modulation (PFM) takes place at light loads. This switchover is affected by a comparator that truncates the low-side switch on-time at the inductor current zero crossing. This mechanism causes the threshold between PFM and PWM operation to coincide with the boundary between continuous and discontinuous inductor-current operation (also known as the critical conduction point). The on-time of PFM is given by:

$$T_{\text{ON-PFM}} = \frac{1}{F_{\text{SW}}} \times \frac{V_{\text{OUT}}}{V_{\text{IN}}}$$

Where  $F_{\text{SW}}$  is the nominal switching frequency of the converter in PWM mode.

The load current at handoff from PFM to PWM mode is given by:

$$\begin{aligned} I_{\text{LOAD (PFM to PWM)}} &= \frac{1}{2} \times \frac{V_{\text{IN}} - V_{\text{OUT}}}{L} \times T_{\text{ON-PFM}} \\ &= \frac{V_{\text{IN}} - V_{\text{OUT}}}{2L} \times \frac{1}{F_{\text{SW}}} \times \frac{V_{\text{OUT}}}{V_{\text{IN}}} \end{aligned}$$

### Forced-PWM Mode

The Forced-PWM mode disables the zero-crossing comparator, which truncates the low-side switch on-time at the inductor current zero crossing. This causes the low-side gate-drive waveform to become the complement of the high-side gate-drive waveform. This in turn causes the inductor current to reverse at light loads while UG maintains a duty factor of  $V_{\text{OUT}}/V_{\text{IN}}$ . The benefit of Forced-PWM mode is to keep the switching frequency fairly constant. The Forced-PWM mode is most useful for reducing audio frequency noise, improving load-transient response, and providing sink-current capability for dynamic output voltage adjustment.

When  $V_{\text{PFM}}$  is above the PFM high threshold (2.5V, minimum), the converter is in forced-PWM mode. When  $V_{\text{PFM}}$  is below the PFM low threshold (0.5V, maximum), the chip is in automatic PFM/PWM Mode.

### Power-On-Reset

A Power-On-Reset (POR) function is designed to prevent wrong logic controls when the VCC voltage is low. The POR function continually monitors the bias supply voltage on the VCC pin if at least one of the enable pins is set high. When the rising VCC voltage reaches the rising POR voltage threshold (4.35V, typical), the POR signal goes high and the chip initiates soft-start operations. Should this voltage drop lower than 4.25V (typical), the POR disables the chip.

### En Pin Control

When  $V_{\text{EN}}$  is above the EN high threshold (1.5V, minimum), the converter is enabled. When  $V_{\text{EN}}$  is below the EN low threshold (0.5V, maximum), the chip is in the shutdown and only low leakage current is taken from VCC.

## Function Description (Cont.)

### Soft-Start

The APW8714E provides the programmed soft-start function to limit the inrush current. The soft-start time can be programmed by the external capacitor between SS and GND. Typical charge current is 10 $\mu$ A, and the soft-start time can be calculated by the following formula:

$$T_{SS} = (C_{SS} \times V_{SS}) / I_{SS}$$

$$V_{OUT} \text{ ready, } V_{SS} = 1V : T_{SS} (\mu s) = 100 \times C_{SS} (\text{nF})$$

$$\text{POK ready, } V_{SS} = 3.3V : T_{SS} (\mu s) = 330 \times C_{SS} (\text{nF})$$

The APW8714E integrates soft-start circuits to ramp up the output voltage of the converter to the programmed regulation set point at a predictable slew rate. The slew rate of output voltage is internally controlled to limit the inrush current through the output capacitors during soft-start process. When the EN pin is pulled above the rising EN threshold voltage, the device initiates a soft-start process to ramp up the output voltage.

During soft-start stage before the POK pin is ready, the under voltage protection is prohibited. The over voltage and current limit protection functions are enabled. If the output capacitor has residue voltage before startup, both low-side and high-side MOSFETs are in off-state until the soft start voltage equal the  $V_{FB}$  voltage. This will ensure the output voltage starts from its existing voltage level.

In the event of under-voltage, over-temperature or shutdown, the chip enables the soft-stop function. The soft-stop function discharges the output voltages using an internal MOSFET.

### Power Good Indicator

POK is actively held low in shutdown and soft-start status. In the soft-start process, the POK is an open-drain. When the soft-start is finished, the POK is released. In normal operation, the POK window is from 90% to 125% of the converter reference voltage. When the output voltage has to stay within this window, POK signal will become high. When the output voltage outruns 90% or 125% of the target voltage, POK signal will be pulled low immediately. In order to prevent false POK drop, capacitors need to parallel at the output to confine the voltage deviation with severe load step transient.

### Under-Voltage Protection (UVP)

In the process of operation, if a short circuit occurs, the output voltage will drop quickly. When load current is bigger than current limit threshold value, the output voltage will fall out of the required regulation range. The under-voltage protection circuit continually monitors the FB voltage after soft-start is completed. If a load step is strong enough to pull the output voltage lower than the under voltage threshold, the under voltage threshold is 70% of the nominal output voltage, the internal UVP delay counter starts to count. After 16 $\mu$ s de-bounce time, the device turns off both high side and low-side MOSFET with latched. Toggling enable pin to low, or recycling VIN, will clear the latch and bring the chip back to operation.

### Over-Voltage Protection (OVP)

The over voltage function monitors the output voltage by FB pin. Should the FB voltage increase over 125% of the reference voltage due to the high-side MOSFET failure or for other reasons, the over voltage protection comparator designed with a 3 $\mu$ s noise filter will force the low-side MOSFET gate driver fully turn on and latch high. This action actively pulls down the output voltage.

This OVP scheme only clamps the voltage overshoot, and does not invert the output voltage when otherwise activated with a continuously high output from low-side MOSFET driver. It's a common problem for OVP schemes with a latch. Once an over-voltage fault condition is set, it can only be reset by toggling EN or VIN power-on-reset signal.

### Current Limit

The current limit circuit employs a "valley" current-sensing algorithm (See Figure 1). The APW8714E uses the low-side MOSFET's  $R_{DS(ON)}$  of the synchronous rectifier as a current-sensing element. If the magnitude of the current-sense signal at LX pin is above the current-limit threshold 7A(minimum), the PWM is not allowed to initiate a new cycle. The actual peak current is greater than the current-limit threshold by an amount equal to the inductor ripple current. Therefore, the exact current-limit characteristic and maximum load capability are a function of the sense resistance, inductor value, and input voltage.

**Function Description (Cont.)**

**Current Limit( Cont.)**

Figure 1. Current Limit algorithm

The PWM controller uses the low-side MOSFET’s on-resistance  $R_{DS(ON)}$  to monitor the current for protection against shorted outputs. The MOSFET’s  $R_{DS(ON)}$  is varied by temperature and gate to source voltage, the user should determine the maximum  $R_{DS(ON)}$  in manufacture’s datasheet.

The PCB layout guidelines should ensure that noise and DC errors do not corrupt the current-sense signals at LX. Place the hottest power MOSEFT’s as close to the IC as possible for best thermal coupling. When combined with the under-voltage protection circuit, this current-limit method is effective in almost every circumstance.

**Over-Temperature Protection (OTP)**

When the junction temperature increases above the rising threshold temperature  $T_{OTR}$ , the IC will enter the over temperature protection state that suspends the PWM, which forces the UG and LG gate drivers output low. The thermal sensor allows the converters to start a start-up process and regulate the output voltage again after the junction temperature cools by 45°C. The OTP designed with a 45°C hysteresis lowers the average  $T_j$  during continuous thermal overload conditions, which increases life-time of the APW8714E.

**Programming the On-Time Control and PWM Switching Frequency**

The APW8714E does not use a clock signal to produce PWM. The device uses the constant on-time control architecture to produce pseudo-fixed frequency with input voltage feed-forward. The on-time pulse width is proportional to output voltage  $V_{OUT}$  and inverse proportional to input voltage  $V_{IN}$ . In PWM, the on-time calculation is written as below equation.

$$T_{ON} = \frac{26.3 \times 10^{-12} \times R_{TON} (\Omega)}{V_{IN} (V)} \dots\dots\dots(1)$$

$$T_{ON} = \frac{21 \times 10^{-12} \times R_{TON} (\Omega)}{(V_{IN} - 1)(V)} + 30(ns) \dots\dots\dots(2)$$

Where:

$R_{TON}$  is the resistor connected from TON pin to VIN pin. Furthermore, The approximate PWM switching frequency is written as:

$$T_{ON} = \frac{D}{F_{SW}}, F_{SW} = \frac{V_{OUT}/V_{IN}}{T_{ON}}$$

Where:

$F_{SW}$  is the PWM switching frequency.

It is useful to use formula (1) to set an accurate switching frequency for low duty application if the duty is less than 15% ( $D < 0.15$ ). However, when the duty is more than 15% ( $D > 0.15$ ), the formula (2) is suggested to cover the high duty application.

## Application Information

### Output Voltage Selection

The output voltage is adjustable from 0.8V to 12V with a resistor-divider connected with FB, GND, and converter's output. Using 1% or better resistors for the resistor-divider is recommended. The output voltage is determined by:

$$V_{OUT} = 0.8 \times \left(1 + \frac{R_{TOP}}{R_{GND}}\right)$$

Where 0.8 is the reference voltage,  $R_{TOP}$  is the resistor connected from converter's output to FB, and  $R_{GND}$  is the resistor connected from FB to GND. Suggested  $R_{GND}$  is in the range from 1k to 100k. To prevent stray pickup, locate resistors  $R_{TOP}$  and  $R_{GND}$  close to APW8714E.

### Output Inductor Selection

The duty cycle (D) of a buck converter is the function of the input voltage and output voltage. Once an output voltage is fixed, it can be written as:

$$D = \frac{V_{OUT}}{V_{IN}}$$

The inductor value (L) determines the inductor ripple current,  $I_{RIPPLE}$ , and affects the load transient response. Higher inductor value reduces the inductor's ripple current and induces lower output ripple voltage. The ripple current and ripple voltage can be approximated by:

$$I_{RIPPLE} = \frac{V_{IN} - V_{OUT}}{F_{SW} \times L} \times \frac{V_{OUT}}{V_{IN}}$$

Where  $F_{SW}$  is the switching frequency of the regulator. Although the inductor value and frequency are increased and the ripple current and voltage are reduced, a tradeoff exists between the inductor's ripple current and the regulator load transient response time.

A smaller inductor will give the regulator a faster load transient response at the expense of higher ripple current. Increasing the switching frequency ( $F_{SW}$ ) also reduces the ripple current and voltage, but it will increase the switching loss of the MOSFETs and the power dissipation of the converter. The maximum ripple current occurs at the maximum input voltage.

A good starting point is to choose the ripple current to be approximately 30% of the maximum output current. Once the inductance value has been chosen, selecting an inductor that is capable of carrying the required peak current without going into saturation. In some types of inductors, especially core that is made of ferrite, the ripple current will increase abruptly when it saturates. This results in a larger output ripple voltage. Besides, the inductor needs to have low DCR to reduce the loss of efficiency.

### Output Capacitor Selection

Output voltage ripple and the transient voltage deviation are factors that have to be taken into consideration when selecting an output capacitor. Higher capacitor value and lower ESR reduce the output ripple and the load transient drop. Therefore, selecting high performance low ESR capacitors is recommended for switching regulator applications. In addition to high frequency noise related to MOSFET turn-on and turnoff, the output voltage ripple includes the capacitance voltage drop  $\Delta V_{C_{OUT}}$  and ESR voltage drop  $\Delta V_{ESR}$  caused by the AC peak-to-peak inductor's current. These two voltages can be represented by:

$$\Delta C_{OUT} = \frac{I_{RIPPLE}}{8 \times C_{OUT} \times F_{SW}}$$

$$\Delta V_{ESR} = I_{RIPPLE} \times R_{ESR}$$

These two components constitute a large portion of the total output voltage ripple. In some applications, multiple capacitors have to be paralleled to achieve the desired ESR value. If the output of the converter has to support another load with high pulsating current, more capacitors are needed in order to reduce the equivalent ESR and suppress the voltage ripple to a tolerable level. A small decoupling capacitor (1 $\mu$ F) in parallel for bypassing the noise is also recommended, and the voltage rating of the output capacitors are also must be considered.

To support a load transient that is faster than the switching frequency, more capacitors are needed for reducing the voltage excursion during load step change. Another aspect of the capacitor selection is that the total AC current going through the capacitors has to be less than the rated RMS current specified on the capacitors in order to prevent the capacitor from over-heating.

## Application Information (Cont.)

### Input Capacitor Selection

The input capacitor is chosen based on the voltage rating and the RMS current rating. For reliable operation, selecting the capacitor voltage rating to be at least 1.3 times higher than the maximum input voltage. The maximum RMS current rating requirement is approximately  $I_{OUT}/2$ , where  $I_{OUT}$  is the load current. During power-up, the input capacitors have to handle great amount of surge current. For low-duty notebook applications, ceramic capacitor is recommended. The capacitors must be connected between the drain of high-side MOSFET and the source of low-side MOSFET with very low-impedance PCB layout.

### Thermal Consideration

Because the APW8714E build-in high-side and low-side MOSFET, the heat dissipated may exceed the maximum junction temperature of the part in applications. If the junction temperature reaches approximately 150°C, both power switches will be turned off and the LX node will become high impedance. To avoid the APW8714E from exceeding the maximum junction temperature, the user will need to do some thermal analysis. The goal of the thermal analysis is to determine whether the power dissipated exceeds the maximum junction temperature of the part. The main power dissipated by the part is approximated:

$$P_{UPPER} = I_{OUT}^2(1+TC)(R_{DS(ON)})D + 0.5(I_{OUT})(V_{IN})(t_{SW})F_{SW}$$

$$P_{LOWER} = I_{OUT}^2(1+TC)(R_{DS(ON)})(1-D)$$

$I_{OUT}$  is the load current

TC is the temperature dependency of  $R_{DS(ON)}$

$F_{SW}$  is the switching frequency

$t_{SW}$  is the switching interval

D is the duty cycle

Note that both internal MOSFETs have conduction losses while the upper MOSFET include an additional transition loss. The switching interval,  $t_{SW}$ , is the function of the reverse transfer capacitance  $C_{RSS}$ . The (1+TC) term factors in the temperature dependency of the  $R_{DS(ON)}$  and can be extracted from the " $R_{DS(ON)}$  vs. Temperature" curve of the power MOSFET. In APW8714E case, the  $R_{DS(ON)}$  is about 30mΩ from specification table.

### Layout Consideration

In any high switching frequency converter, a correct layout is important to ensure proper operation of the regulator. With power devices switching at higher frequency, the resulting current transient will cause voltage spike across the interconnecting impedance and parasitic circuit elements. As an example, consider the turn-off transition of the PWM MOSFET. Before turn-off condition, the MOSFET is carrying the full load current. During turn-off, current stops flowing in the MOSFET and is freewheeling by the low side MOSFET and parasitic diode. Any parasitic inductance of the circuit generates a large voltage spike during the switching interval. In general, using short and wide printed circuit traces should minimize interconnecting impedances and the magnitude of voltage spike. Besides, signal and power grounds are to be kept separate and finally combined using ground plane construction or single point grounding. The best tie-point between the signal ground and the power ground is at the negative side of the output capacitor on each channel, where there is less noise. Noisy traces beneath the IC are not recommended. Below is a checklist for your layout:

- Keep the switching nodes (BOOT and LX) away from sensitive small signal nodes since these nodes are fast moving signals. Therefore, keep traces to these nodes as short as possible and there should be no other weak signal traces in parallel with these traces on any layer.
- The large layout plane between the drain of the MOSFETs (VIN and LX nodes) can get better heat sinking.
- The current sense resistor should be close to OCSET pin to avoid parasitic capacitor effect and noise coupling.
- Decoupling capacitors, the resistor-divider, and boot capacitor should be close to their pins.
- The output bulk capacitors should be close to the loads. The input capacitor's ground should be close to the grounds of the output capacitors.
- Locate the resistor-divider close to the FB pin to minimize the high impedance trace. In addition, FB pin traces can't be close to the switching signal traces (BOOT and LX).
