## Function Description

### Voltage Reference

A 2.5V reference regulator supplies FP6112 internal circuits and uses a resistive divider to provide 0.8V precision reference voltage on the non-inverting terminal of error amplifier.

### Error Amplifier

The error amplifier compares a sample of the DC-DC converter output voltage to the 0.8V ( $V_{REF}$ ) reference and generates an error signal for the PWM comparator. Output voltage of the DC-DC converter is setting by the resistor divider with following expression (see Figure 1)

$$V_{OUT} = \left(1 + \frac{R_2}{R_1}\right) \times V_{REF}$$

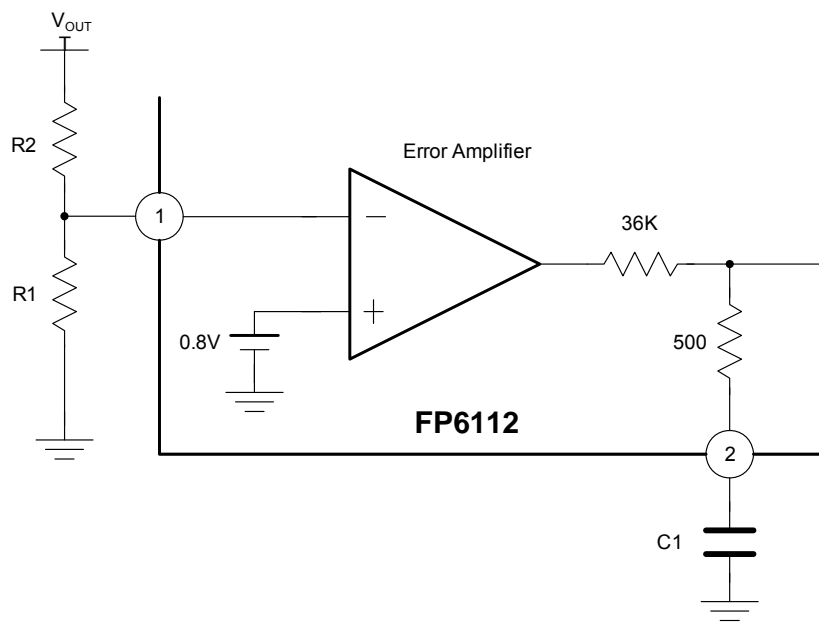

Figure 1 Error Amplifier with Feedback resistance divider

The recommended resistor value is summarized below:

$V_{OUT}$ (V)	$R_1$ (k $\Omega$ )	$R_2$ (k $\Omega$ )
1.8	2.4k	3k
2.5	3.2k	6.8k
3.3	1.5k	4.7k
5	2k	10.5k

**Oscillator**

The fixed frequency is generated by an internal RC oscillator. Its typical value is 320KHz in normal operation and 30KHz in short circuit condition.

**Thermal Protection**

When a heavy loading draws current from the regulator, the chip temperature will rise. Once the junction temperature exceeds 150°C, FP6112 thermal protection function will be triggered and the LX output will be turned off. When junction temperature is lower, FP6112 starts again and enable LX pin output.

**Over Current Protection**

The FP6112 uses cycle-by-cycle current limit to protect the internal power switch. During each switching cycle, a current limit comparator detects if the power switch current exceeds the internal setting current, and begins over current protection decrease the oscillator frequency to prevent the driver from burning out.

## Application Information

### Input Capacitor Selection

The input capacitor must be connected between the  $V_{CC}$  and GND pin of the FP6112 to maintain steady input voltage and filter out the pulsing input current. The voltage rating of input capacitor must be greater than maximum input voltage plus ripple voltage.

In switch mode, the input current is discontinuous in a buck converter. The source current of the high-side MOSFET is a square wave. To prevent large voltage transients, a low ESR input capacitor sized for the maximum RMS current must be used. The RMS value of input capacitor current can be calculated by:

$$I_{RMS} = I_{O\_MAX} \sqrt{\frac{V_O}{V_{IN}} \left(1 - \frac{V_O}{V_{IN}}\right)}$$

It can be seen that when  $V_O$  is half of  $V_{IN}$ ,  $C_{IN}$  is under the worst current stress. The worst current stress on  $C_{IN}$  is  $I_{O\_MAX} / 2$ .

### Inductor Selection

The value of the inductor is selected based on the maximum tolerant ripple current. Large inductance gives low inductor ripple current and small inductance result in high ripple current. However, the larger value inductor usually has a larger physical size, higher series resistance, and lower saturation current. On the experience, the value is to allow the peak-to-peak ripple current in the inductor to be 10%~20% maximum load current. The inductance value can be calculated by:

$$L = \frac{(V_{IN} - V_O) V_O}{f \times \Delta I_L} = \frac{(V_{IN} - V_O) V_O}{f \times [2 \times (10\% \sim 20\%) I_O]}$$

The inductor ripple current can be calculated by:

$$\Delta I_L = \frac{V_O}{f \times L} \times \left(1 - \frac{V_O}{V_{IN}}\right)$$

Choose an inductor that does not saturate under the worst-case load conditions, which is the load current plus half the peak-to-peak inductor ripple current, even at the highest operating temperature. The peak inductor current is:

$$I_{L\_PEAK} = I_O + \frac{\Delta I_L}{2}$$

The inductors in different shape and style are available from manufacturers. Shielded inductors are small and radiate less EMI issue. But they cost more than unshielded inductors. The choice depends on EMI requirement, price and size.

Inductor Value (μH)	Dimensions(mm)	Component Supplier	Model
10	10.3×10.3×4.0	FENG-JUI	TPRH10D40-10R
10	10.1×10.1×3.0	Sumida	CDRH104R
15	10.3×10.3×4.0	FENG-JUI	TPRH10D40-15R

### Output Capacitor Selection

The output capacitor is required to maintain the DC output voltage. Low ESR capacitors are preferred to keep the output voltage ripple low. In a buck converter circuit, output ripple voltage is determined by inductor value, switching frequency, output capacitor value and ESR. The output ripple is determined by:

$$\Delta V_O = \Delta I_L \times \left( \text{ESR}_{C_{OUT}} + \frac{1}{8 \times f \times C_{OUT}} \right)$$

Where  $f$  = operating frequency,  $C_{OUT}$  = output capacitance and  $\Delta I_L$  = ripple current in the inductor. For a fixed output voltage, the output ripple is highest at maximum input voltage since  $\Delta I_L$  increases with input voltage.

### Using Ceramic Input and Output Capacitors

Care must be taken when ceramic capacitors are used at the input and the output. When a ceramic capacitor is used at the input and the power is supplied by a wall adapter through long wires, a load step at the output can induce ringing at the input,  $V_{IN}$ . In best condition, this ringing can couple to the output and be mistaken as loop instability. In worst condition, a sudden inrush of current through the long wires can potentially generate a voltage spike at  $V_{IN}$ , which may large enough to damage the part. When choosing the input and output ceramic capacitors, choose the one with X5R or X7R dielectric formulations. These dielectrics have the best temperature and voltage characteristics of all the ceramics for a given value and size.

### PC Board Layout Checklist

1. The power traces, consisting of the GND, SW and  $V_{IN}$  traces, should be kept short, direct and wide.
2. Place  $C_{IN}$  near  $V_{CC}$  pin as closely as possible to maintain input voltage steady and filter out the pulsing input current.

3. The resistive divider  $R_1$  and  $R_2$  must be connected to FB pin directly and as closely as possible.
4. FB is a sensitive node. Please keep it away from switching node SW. A good approach is to route the feedback trace on another layer and have a ground plane between the top and feedback trace routing layer. This reduces EMI radiation on to the DC-DC converter's own voltage feedback trace.
5. Keep the GND plates of  $C_{IN}$  and  $C_{OUT}$  as close as possible. Then connect this to the ground plane (if one is used) with several vias. This reduces ground plane noise by preventing the switching currents from circulating through the ground plane. It also reduces ground bounce at the FP6112 GND pin by giving it a low impedance ground connection.
